

CoinPilot

Coincheck spot trading bot with on-chain performance proof for friends

The Problem & Our Solution

Friends who trade crypto together have no way to verify each other's claimed returns or trust shared strategies.

- Trading bots on centralized exchanges are black boxes—no public proof of performance
- Friend groups share strategies but can't audit real results, only screenshots
- CoinPilot logs every trade's hash and PnL snapshot on Solana for tamper-proof proof
- Friends can follow each other's bot performance on a shared, verifiable dashboard
- Profit-split vault lets groups pool strategies without exposing exchange API keys

How It Works

CoinPilot connects Coincheck execution with Solana's on-chain transparency, so every trade is automated and provable.

- User sets a strategy (MA cross, RSI) and risk limits like max position size and stop-loss
- Bot executes spot buy/sell automatically via the Coincheck API
- Each executed trade's timestamp, pair, and PnL are recorded on a Solana program
- Shared React dashboard pulls on-chain data to show every friend's real performance
- A simple vault contract splits profits for pooled strategies, no API key sharing needed

Built with

Solana, Coincheck API, Node.js, Anchor (Solana), React, PostgreSQL, WebSocket price feeds

Why Now & What's Next

Retail trading automation is booming in Japan, and informal friend-group trading needs a trust layer that only on-chain proof can give.

- Rising retail interest in automated crypto trading in Japan creates demand now
- CEX execution plus on-chain transparency closes the trust gap in shared strategies
- Next: add more exchanges like Binance and bitFlyer beyond Coincheck
- Next: build a strategy marketplace to publish and subscribe to verified bots
- Next: introduce staking-based reputation for strategy creators
